Alternative tests

When there isn't sufficient normality

- ullet When your samples are not normal enough, cannot use t procedures
- Sometimes transforming the data (eg taking logs of all the values) will help
- Or, use test with no assumptions about normality:
 - ▶ for one sample, use sign test for median
 - ▶ for two samples, use *Mood's median test*
 - ▶ for matched pairs, use sign test on differences.

Alternative tests 2 / 56

One-sample: the IRS data

- The IRS ("Internal Revenue Service") is the US authority that deals with taxes (like Revenue Canada).
- One of their forms is supposed to take no more than 160 minutes to complete. A citizen's organization claims that it takes people longer than that on average.
- Sample of 30 people; time to complete form recorded.
- \bullet Read in data, and do t-test of $H_0: \mu=160$ vs. $H_a: \mu>160.$
- Only one column, so pretend it is delimited by something.

Alternative tests 3 / 56

Packages

```
library(tidyverse)
library(smmr)
```

• installation instructions for smmr later

Alternative tests 4 / 56

Read in data

```
my_url <- "http://ritsokiguess.site/datafiles/irs.txt"
irs <- read_csv(my_url)
irs</pre>
```

```
# A tibble: 30 x 1

# i 20 more rows
```

Alternative tests 5 / 56

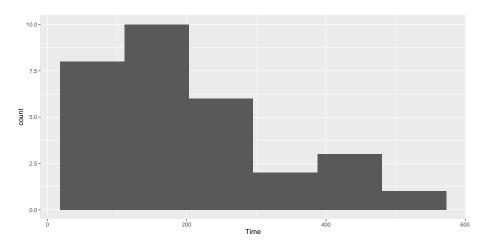

Test whether mean is 160 or greater

One Sample t-test

Reject null; mean (for all people to complete form) greater than 160.

Alternative tests 6 / 56

But, look at a graph

Alternative tests 7 / 56

Comments

- Skewed to right.
- Should look at median, not mean.

Alternative tests 8 / 56

The sign test

- But how to test whether the median is greater than 160?
- Idea: if the median really is 160 (H_0 true), the sampled values from the population are equally likely to be above or below 160.
- If the population median is greater than 160, there will be a lot of sample values greater than 160, not so many less. Idea: test statistic is number of sample values greater than hypothesized median.

Alternative tests 9 / 56

Getting a P-value for sign test 1/3

- How to decide whether "unusually many" sample values are greater than 160? Need a sampling distribution.
- If H_0 true, pop. median is 160, then each sample value independently equally likely to be above or below 160.
- So number of observed values above 160 has binomial distribution. with n=30 (number of data values) and p=0.5 (160 is hypothesized to be *median*).

10 / 56

Getting P-value for sign test 2/3

Count values above/below 160:

```
irs %>% count(Time > 160)
```

• 17 above, 13 below. How unusual is that? Need a binomial table.

Alternative tests 11 / 56

Getting P-value for sign test 3/3

 \bullet R function dbinom gives the probability of eg. exactly 17 successes in a binomial with n=30 and p=0.5 :

```
dbinom(17, 30, 0.5)
```

[1] 0.1115351

• but we want probability of 17 *or more*, so get all of those, find probability of each, and add them up:

```
tibble(x=17:30) %>%
  mutate(prob=dbinom(x, 30, 0.5)) %>%
  summarize(total=sum(prob))
```

```
# A tibble: 1 x 1
  total
  <dbl>
1 0.292
```

Alternative tests 12 / 56

... or

use cumulative distribution

[1] 0.8192027

and hence (note first input):

[1] 0.2923324

This last is $P(X \ge 17) = P(X > 16)$.

Alternative tests 13 / 56

Using my package smmr

• I wrote a package smmr to do the sign test (and some other things). Installation is non-standard:

```
install.packages("smmr", repos = "nxskok.r-universe.dev")
```

• Then load it:

```
library(smmr)
```

Alternative tests 14 / 56

smmr for sign test

 smmr's function sign_test needs three inputs: a data frame, a column and a null median:

```
sign_test(irs, Time, 160)
$above_below
below above
   13 17
$p_values
 alternative p_value
       lower 0.8192027
       upper 0.2923324
   two-sided 0.5846647
```

Alternative tests 15 / 56

Comments (1/4)

- Testing whether population median *greater than* 160, so want *upper-tail* P-value 0.2923. Same as before.
- Also get table of values above and below; this too as we got.

Alternative tests 16 / 56

Comments (2/4)

P-values are:

Test	P-value
\overline{t}	0.0392
Sign	0.2923

• These are very different: we reject a mean of 160 (in favour of the mean being bigger), but clearly *fail* to reject a median of 160 in favour of a bigger one.

Alternative tests 17 / 56

Comments (3/4)

• Why is that? Obtain mean and median:

Alternative tests 18 / 56

Comments (4/4)

- The mean is pulled a long way up by the right skew, and is a fair bit bigger than 160.
- The median is quite close to 160.
- We ought to be trusting the sign test and not the t-test here (median and not mean), and therefore there is no evidence that the "typical" time to complete the form is longer than 160 minutes.
- Having said that, there are clearly some people who take a lot longer than 160 minutes to complete the form, and the IRS could focus on simplifying its form for these people.
- In this example, looking at any kind of average is not really helpful; a better question might be "do an unacceptably large fraction of people take longer than (say) 300 minutes to complete the form?": that is, thinking about worst-case rather than average-case.

Alternative tests 19 / 56

CI for median 1/2

- The sign test does not naturally come with a confidence interval for the median.
- So we use the "duality" between test and confidence interval to say: the (95%) confidence interval for the median contains exactly those values of the null median that would not be rejected by the two-sided sign test (at $\alpha=0.05$).

Alternative tests 20 / 56

CI for median 2/2

• Precisely: Let $C=100(1-\alpha)$, so C% gives corresponding CI to level- α test. Then following always true. (Symbol \iff means "if and only if".)

Test decision		Confidence interval
Reject H_0 at level α	\iff	$C\%$ CI does not contain H_0 value
Do not reject ${\cal H}_0$ at level α	\iff	$C\%$ CI contains H_0 value

- Idea:
 - "Plausible" parameter value inside CI, not rejected;
 - "Implausible" parameter value outside CI, rejected.

Alternative tests 21 / 56

The value of this

- If you have a test procedure but no corresponding CI:
- you make a CI by including all the parameter values that would not be rejected by your test.
- Use:
 - $\alpha = 0.01$ for a 99% CI,
 - $\sim \alpha = 0.05$ for a 95% CI.
 - $\sim \alpha = 0.10$ for a 90% CI, and so on.

Alternative tests 22 / 56

For our data

- The procedure is to try some values for the null median and see which ones are inside and which outside our CI.
- smmr has pval_sign that gets just the 2-sided P-value:

```
pval_sign(160, irs, Time)
```

[1] 0.5846647

• Try a couple of null medians:

```
pval_sign(200, irs, Time)
```

[1] 0.3615946

```
pval_sign(300, irs, Time)
```

[1] 0.001430906

So 200 inside the 95% CI and 300 outside.

Alternative tests 23 / 56

Doing a whole bunch

```
(d <- tibble(null_median=seq(100,300,20)))
```

```
A tibble: 11 x 1
   null_median
          <dbl>
            100
            120
 3
            140
            160
 5
            180
 6
            200
            220
8
            240
9
            260
10
            280
11
            300
```

Alternative tests 24 / 56

... and then

"for each null median, run the function pval_sign for that null median and get the P-value":

```
d %>% rowwise() %>%
mutate(p_value = pval_sign(null_median, irs, Time))
```

Alternative tests 25 / 56

Results

```
# A tibble: 11 x 2
# Rowwise:
   null_median p_value
         <dbl>
                   <dbl>
 1
            100 0.000325
           120 0.0987
 3
           140 0.200
           160 0.585
 5
           180 0.856
 6
           200 0.362
           220 0.0428
8
           240 0.0161
9
           260 0.00522
10
           280 0.00143
11
           300 0.00143
```

Alternative tests 26 / 56

Make it easier for ourselves

```
d %>% rowwise() %>%
 mutate(p_value = pval_sign(null_median, irs, Time)) %>%
 mutate(in_out = ifelse(p_value > 0.05, "inside", "outside"))
# A tibble: 11 x 3
# Rowwise:
  null median p value in out
        <dbl> <dbl> <chr>
          100 0.000325 outside
          120 0.0987
                       inside
3
          140 0.200
                       inside
4
          160 0.585
                       inside
5
          180 0.856
                       inside
6
          200 0.362
                       inside
          220 0.0428
                       outside
          240 0.0161 outside
          260 0.00522
                       outside
10
          280 0.00143
                       outside
11
          300 0.00143
                       outside
```

Alternative tests 27 / 56

Confidence interval for median?

- 95% CI to this accuracy from 120 to 200.
- Can get it more accurately by looking more closely in intervals from 100 to 120, and from 200 to 220.

Alternative tests 28 / 56

A more efficient way: bisection

• Know that top end of CI between 200 and 220:

```
lo <- 200
hi <- 220
```

• Try the value halfway between: is it inside or outside?

```
try <- (lo + hi) / 2
try</pre>
```

[1] 210

```
pval_sign(try,irs,Time)
```

[1] 0.09873715

• Inside, so upper end is between 210 and 220. Repeat (over):

Alternative tests 29 / 56

... bisection continued

```
lo <- try
try <- (lo + hi) / 2
try
```

[1] 215

```
pval_sign(try, irs, Time)
```

[1] 0.06142835

- 215 is inside too, so upper end between 215 and 220.
- Continue until have as accurate a result as you want.

Alternative tests 30 / 56

Bisection automatically

 A loop, but not a for since we don't know how many times we're going around. Keep going while a condition is true:

```
10 = 200
hi = 220
while (hi - lo > 1) { # replace 1 by desired accuracy
  try = (hi + lo) / 2
  ptry = pval sign(try, irs, Time)
  print(c(try, ptry))
  if (ptry \ll 0.05)
   hi = try
  else
    lo = try
```

Alternative tests 31 / 56

The output from this loop

```
      [1]
      210.00000000
      0.09873715

      [1]
      215.00000000
      0.06142835

      [1]
      217.50000000
      0.04277395

      [1]
      216.25000000
      0.04277395

      [1]
      215.62500000
      0.04277395
```

• 215 inside, 215.625 outside. Upper end of interval to this accuracy is 215.

Alternative tests 32 / 56

Using smmr

• smmr has function ci_median that does this (by default 95% CI):

```
ci_median(irs, Time)
```

[1] 119.0065 214.9955

- Uses a more accurate bisection than we did.
- Or get, say, 90% CI for median:

```
ci_median(irs, Time, conf.level=0.90)
```

[1] 123.0031 208.9960

• 90% CI is shorter, as it should be.

Alternative tests 33 / 56

Bootstrap

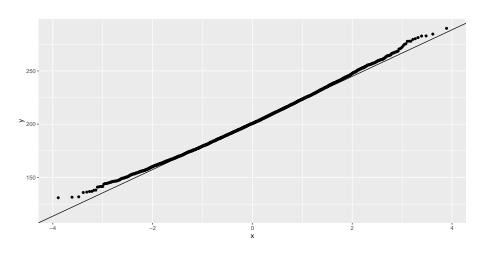

- but, was the sample size (30) big enough to overcome the skewness?
- Bootstrap, again:

```
tibble(sim = 1:10000) %>%
  rowwise() %>%
  mutate(my sample = list(sample(irs$Time, replace = TRUE))) *
  mutate(my mean = mean(my sample)) %>%
  ggplot(aes(sample = my mean)) +
    stat qq() + stat qq line() -> g
```

Alternative tests 34 / 56

The sampling distribution

g

Alternative tests 35 / 56

Comments

- A little skewed to right, but not nearly as much as I was expecting.
- The t-test for the mean might actually be OK for these data, if the mean is what you want.
- In actual data, mean and median very different; we chose to make inference about the median.
- Thus for us it was right to use the sign test.

Alternative tests 36 / 56

Two samples: Mood's median test

- If normality fails (for one or both of the groups), what do we do then?
- Again, can compare medians: use the thought process of the sign test, which does not depend on normality and is not damaged by outliers.
- A suitable test called Mood's median test.
- Before we get to that, a diversion.

Alternative tests 37 / 56

The chi-squared test for independence

Suppose we want to know whether people are in favour of having daylight savings time all year round. We ask 20 males and 20 females whether they each agree with having DST all year round ("yes") or not ("no").

Alternative tests 38 / 56

Some of the data:

```
my_url <- "http://ritsokiguess.site/datafiles/dst.txt"
dst <- read_delim(my_url," ")
dst %>% slice_sample(n = 10)
```

```
A tibble: 10 \times 2
  gender agree
  <chr> <chr>
1 male yes
2 male
          yes
3 female yes
4 male
          yes
5 male
         yes
6 male
         yes
7 male
         yes
8 male
         no
9 male
         yes
10 male
          yes
```

Alternative tests 39 / 56

... continued

Count up individuals in each category combination, and arrange in contingency table:

```
tab <- with(dst, table(gender, agree))
tab</pre>
```

```
agree
gender no yes
female 11 9
male 3 17
```

- Most of the males say "yes", but the females are about evenly split.
- Looks like males more likely to say "yes", ie. an association between gender and agreement.

Alternative tests 40 / 56

... continued

- ullet Test an H_0 of "no association" ("independence") vs. alternative that there is really some association.
- Done with chisq.test.

Alternative tests 41 / 56

...And finally

```
chisq.test(tab, correct=FALSE)
```

Pearson's Chi-squared test

```
data: tab
X-squared = 7.033, df = 1, p-value = 0.008002
```

- Reject null hypothesis of no association (P-value 0.008)
- therefore there is a difference in rates of agreement between (all) males and females (or that gender and agreement are associated).
- Same answers as by hand. (Omitting correct = FALSE uses "Yates correction".

Alternative tests 42 / 56

Mood's median test

- Earlier: compare medians of two groups.
- Sign test: count number of values above and below something (there, hypothesized median).
- Mood's median test:
 - ▶ Find "grand median" of all the data, regardless of group
 - ▶ Count data values in each group above/below grand median.
 - Make contingency table of group vs. above/below.
 - Test for association.

Alternative tests 43 / 56

Why it works

 If group medians equal, each group should have about half its observations above/below grand median. If not, one group will be mostly above grand median and other below.

Alternative tests 44 / 56

Mood's median test for reading data

Find overall median score:

```
kids %>% summarize(med=median(score)) %>% pull(med) -> m
m
```

[1] 47

Make table of above/below vs. group:

```
tab <- with(kids, table(group, score > m))
tab
```

```
group FALSE TRUE
   c 15 8
```

7 14

 Treatment group scores mostly above median, control group scores mostly below, as expected.

The test

Do chi-squared test:

```
chisq.test(tab, correct=FALSE)
```

Pearson's Chi-squared test

```
data: tab
X-squared = 4.4638, df = 1, p-value = 0.03462
```

- Two-sided (tests for any association).
- Here, is reading method better? (one-sided).
- Most of treatment children above overall median, so halve P-value to get 0.017.
- Again, children learn to read better using new method.

Alternative tests 46 / 56

Or by smmr

\$grand_median

above

[1] 47

\$table

• median_test does the whole thing:

```
median_test(kids,score,group)
```

P-value again two-sided.

Comments 1/2

- P-value 0.013 for (1-sided) t-test, 0.017 for (1-sided) Mood median test.
- Like the sign test, Mood's median test doesn't use the data very efficiently (only, is each value above or below grand median).
- Thus, if we can justify doing *t*-test, we should do it. This is the case here.

Alternative tests 48 / 56

Comments 2/2

- The t-test will usually give smaller P-value because it uses the data more efficiently.
- The time to use Mood's median test is if we are definitely unhappy with the normality assumption (and thus the t-test P-value is not to be trusted).
- There is no obvious way to get a confidence interval for the difference between the two medians.

49 / 56

Matched pairs: the pain relief data

Values aligned in columns:

```
my_url <-
   "http://ritsokiguess.site/datafiles/analgesic.txt"
pain <- read_table(my_url)
pain %>% mutate(diff = druga - drugb) -> pain
glimpse(pain)
```

```
Rows: 12
Columns: 4
$ subject <dbl> 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12
$ druga <dbl> 2.0, 3.6, 2.6, 2.6, 7.3, 3.4, 14.9, 6.6, 2.3,
$ drugb <dbl> 3.5, 5.7, 2.9, 2.4, 9.9, 3.3, 16.7, 6.0, 3.8,
$ diff <dbl> -1.5, -2.1, -0.3, 0.2, -2.6, 0.1, -1.8, 0.6, -1.5, -2.0, -2.3,~
```

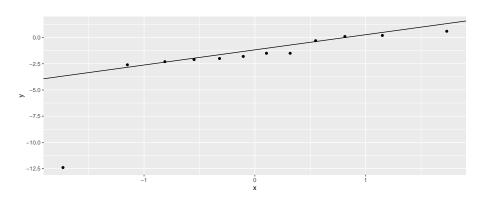

Alternative tests 50 / 56

Assessing normality

- Matched pairs analyses assume (theoretically) that differences normally distributed.
- How to assess normality? A normal quantile plot.

Alternative tests 51 / 56

The normal quantile plot (of differences)

• Points should follow the straight line. Bottom left one way off, so normality questionable here: outlier.

Alternative tests 52 / 56

What to do instead?

- Matched pairs t-test based on one sample of differences
- the differences not normal (enough)
- so do sign test on differences, null median 0:

Alternative tests 53 / 56

... continued

\$above below

```
sign_test(pain, diff, 0)
```

 No evidence of any difference between the drugs (that the median difference is not zero).

Alternative tests 54 / 56

Did we really need to worry about that outlier?

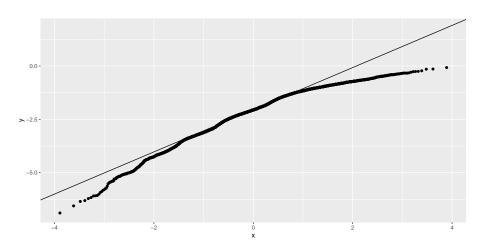

Bootstrap sampling distribution of sample mean differences:

```
tibble(sim = 1:10000) %>%
  rowwise() %>%
  mutate(my_sample = list(sample(pain$diff, replace = TRUE)))
  mutate(my_mean = mean(my_sample)) %>%
  ggplot(aes(sample = my_mean)) + stat_qq() + stat_qq_line()
```

Alternative tests 55 / 56

The normal quantile plot

g

Yes we did need to worry; this is clearly skewed left and not normal.

Alternative tests 56 / 56
