Functions

Functions 1/46

Packages for this section

```
library(tidyverse)
library(broom) # some regression stuff later
```

Functions 2 / 46

Don't repeat yourself

• See this:

```
a < -50
b <- 11
d < -3
as <- sqrt(a - 1)
as
[1] 7
```

```
bs <- sqrt(b - 1)
bs
```

[1] 3.162278

```
ds \leftarrow sqrt(d - 1)
ds
```

[1] 1.414214

What's the problem?

- Same calculation done three different times, by copying, pasting and editing.
- Dangerous: what if you forget to change something after you pasted?
- Programming principle: "don't repeat yourself".
- Hadley Wickham: don't copy-paste more than twice.
- Instead: write a function.

Functions 4 / 46

Anatomy of function

- Header line with function name and input value(s).
- Body with calculation of values to output/return.
- Return value: the output from function. In our case:

```
sqrt_minus_1 <- function(x) {
  ans <- sqrt(x - 1)
  return(ans)
}</pre>
```

or more simply ("the R way", better style)

```
sqrt_minus_1 <- function(x) {
   sqrt(x - 1)
}</pre>
```

If last line of function calculates value without saving it, that value is returned.

Functions 5 / 46

About the input; testing 1/2

[1] 1.414214

- ullet The input to a function can be called anything. Here we called it x. This is the name used inside the function.
- The function is a "machine" for calculating square-root-minus-1. It doesn't do anything until you call it:

```
sqrt_minus_1(50)

[1] 7

sqrt_minus_1(11)

[1] 3.162278

sqrt_minus_1(3)
```

Functions 6 / 46

Testing 2/2

```
q <- 17
sqrt_minus_1(q)</pre>
```

[1] 4

```
sqrt_minus_1("text")
```

Error in x - 1: non-numeric argument to binary operator

• It works! (At least, it works when it should and fails when it should.)

Functions 7 / 46

Vectorization 1/2

• We conceived our function to work on numbers:

```
sqrt_minus_1(3.25)
```

[1] 1.5

• but it actually works on vectors too, as a free bonus of R:

```
sqrt_minus_1(c(50, 11, 3))
```

[1] 7.000000 3.162278 1.414214

or... (over)

Functions 8 / 46

Vectorization 2/2

or even data frames:

 $d \leftarrow tibble(x = 1:2, y = 3:4)$

```
1 0 1.414214
2 1 1.732051
```

Functions 9 / 46

More than one input

 Allow the value to be subtracted, before taking square root, to be input to function as well, thus:

```
sqrt_minus_value <- function(x, d) {
  sqrt(x - d)
}</pre>
```

• Call the function with the x and d inputs in the right order:

```
sqrt_minus_value(51, 2)
```

[1] 7

• or give the inputs names, in which case they can be in any order.

```
sqrt_minus_value(d = 2, x = 51)
```

Γ17 7

Functions 10 / 46

Defaults 1/2

 Many R functions have values that you can change if you want to, but usually you don't want to, for example:

```
x <- c(3, 4, 5, NA, 6, 7)
x
```

[1] 3 4 5 NA 6 7

```
mean(x)
```

[1] NA

```
mean(x, na.rm = TRUE)
```

[1] 5

 By default, the mean of data with a missing value is missing, but if you specify na.rm=TRUE, the missing values are removed before the mean is calculated.

Functions 11 / 46

Defaults 2/2

• In our function, set a default value for d like this:

```
sqrt_minus_value <- function(x, d = 1) {
  sqrt(x - d)
}</pre>
```

• If you specify a value for d, it will be used. If you don't, 1 will be used instead:

```
sqrt_minus_value(51, 2)
```

[1] 7

```
sqrt_minus_value(51)
```

[1] 7.071068

Functions 12 / 46

Catching errors before they happen

• What happened here?

```
sqrt_minus_value(6, 8)
```

```
Warning in sqrt(x - d): NaNs produced
```

[1] NaN

- Message not helpful. Actually, function tried to take square root of negative number.
- In fact, not even error, just warning.
- Check that the square root will be OK first. Here's how:

```
sqrt_minus_value <- function(x, d = 1) {
  stopifnot(x - d >= 0)
  sqrt(x - d)
}
```

Functions 13 / 46

What happens with stopifnot

• This should be good, and is:

```
sqrt_minus_value(8, 6)
```

[1] 1.414214

• This should fail, and see how it does:

```
sqrt_minus_value(6, 8)
```

```
Error in sqrt_minus_value(6, 8): x - d >= 0 is not TRUE
```

- Where the function fails, we get informative error, but if everything good, the stopifnot does nothing.
- stopifnot contains one or more logical conditions, and all of them have to be true for function to work. So put in everything that you want to be true.

Functions 14 / 46

Using R's built-ins

- When you write a function, you can use anything built-in to R, or even any functions that you defined before.
- For example, if you will be calculating a lot of regression-line slopes, you don't have to do this from scratch: you can use R's regression calculations, like this:

```
my_df \leftarrow tibble(x = 1:4, y = c(10, 11, 10, 14))
my_df
```

Functions 15 / 46

Running the regression

```
my_df.1 <- lm(y ~ x, data = my_df)
tidy(my_df.1)</pre>
```

Functions 16 / 46

Pulling out just the slope

Use pluck:

```
tidy(my_df.1) %>% pluck("estimate", 2)
```

[1] 1.1

Functions 17 / 46

Making this into a function

- First step: make sure you have it working without a function (we do)
- Inputs: two, an x and a y.
- Output: just the slope, a number. Thus:

```
slope <- function(xx, yy) {
  y.1 <- lm(yy ~ xx)
  tidy(y.1) %>% pluck("estimate", 2)
}
```

• Check using our data from before: correct:

```
with(my_df, slope(x, y))
```

[1] 1.1

nctions 18 / 46

Passing things on

1m has a lot of options, with defaults, that we might want to change.
 Instead of intercepting all the possibilities and passing them on, we can do this:

```
slope <- function(xx, yy, ...) {
  y.1 <- lm(yy ~ xx, ...)
  tidy(y.1) %>% pluck("estimate", 2)
}
```

• The ... in the header line means "accept any other input", and the ... in the lm line means "pass anything other than x and y straight on to lm".

unctions 19 / 46

Using ...

- One of the things lm will accept is a vector called subset containing the list of observations to include in the regression.
- So we should be able to do this:

```
with(my_df, slope(x, y, subset = 3:4))
```

[1] 4

4 14

Just uses the last two observations in x and y:

• so the slope should be (14-10)/(4-3)=4 and is.

Functions 20 / 46

What happens here?

```
with(my_df, slope(x, y, hair = "spiky"))
```

Warning: In lm.fit(x, y, offset = offset, singular.ok = singular
extra argument 'hair' will be disregarded

[1] 1.1

• Where did the warning come from?

Functions 21 / 46

Running a function for each of several inputs

• Suppose we have a data frame containing several different x's to use in regressions, along with the y we had before:

```
(d \leftarrow tibble(x1 = 1:4, x2 = c(8, 7, 6, 5), x3 = c(2, 4, 6, 9))
```

- Want to use these as different x's for a regression with y from my_df as the response, and collect together the three different slopes.
- Python-like way: a for loop.
- R-like way: map_dbl: less coding, but more thinking.

Functions 22 / 46

The loop way

- "Pull out" column i of data frame d as d %>% pull(i).
- Create empty vector slopes to store the slopes.
- Looping variable i goes from 1 to 3 (3 columns, thus 3 slopes):

```
slopes <- numeric(3)
for (i in 1:3) {
  d %>% pull(i) -> xx
    slopes[i] <- slope(xx, my_df$y)
}
slopes</pre>
```

```
[1] 1.1000000 -1.1000000 0.5140187
```

• Check this by doing the three lms, one at a time.

Functions 23 / 46

The map_dbl way

- In words: for each of these (columns of d), run function (slope) with inputs "it" and y), and collect together the answers.
- Since slope returns a decimal number (a db1), appropriate function-running function is map_db1:

```
map_dbl(d, \(d) slope(d, my_df$y))
```

```
x1 x2 x3
1.1000000 -1.1000000 0.5140187
```

• Same as loop, with a lot less coding.

inctions 24 / 46

Square roots

• "Find the square roots of each of the numbers 1 through 10":

```
x <- 1:10
map_dbl(x, \(x) sqrt(x))</pre>
```

[1] 1.000000 1.414214 1.732051 2.000000 2.236068 2.449490 2.6

[9] 3.000000 3.162278

Functions 25 / 46

Summarizing all columns of a data frame, two ways

• use my d from above:

```
map_dbl(d, \ \ (d) \ mean(d))
 x1 x2 x3
2.50 6.50 5.25
d %>% summarize(across(everything(), \(x) mean(x)))
# A tibble: 1 \times 3
    x1 x2 x3
  <db1> <db1> <db1>
1 2.5 6.5 5.25
```

The mean of each column, with the columns labelled.

Functions 26 / 46

What if summary returns more than one thing?

• For example, finding quartiles:

```
quartiles <- function(x) {
  quantile(x, c(0.25, 0.75))
}
quartiles(1:5)</pre>
```

```
25% 75%
2 4
```

• When function returns more than one thing, map (or map_df) instead of map_dbl.

Functions 27 / 46

Map results

• Try:

```
map(d, \(d) quartiles(d)) -> e
e
```

```
25% 75%
1.75 3.25
$x2
```

\$x1

25% 75% 5.75 7.25

\$x3 25% 75% 3.50 6.75

A list.

Functions 28 / 46

Or

• Better: pretend output from quartiles is one-row data frame:

```
map_df(d, \(d) quartiles(d))
```

Functions 29 / 46

Or even

2 5.75 7.25 3 3.5 6.75

```
d %>% map_df(\(d) quartiles(d))

# A tibble: 3 x 2
   `25%` `75%`
   <dbl> <dbl>
1 1.75 3.25
```

Functions 30 / 46

Comments

- This works because the implicit first thing in map is (the columns of) the data frame that came out of the previous step.
- These are 1st and 3rd quartiles of each column of d, according to R's default definition (see help for quantile).

Functions 31 / 46

Map in data frames with mutate

map can also be used within data frames to calculate new columns.
 Let's do the square roots of 1 through 10 again:

```
d <- tibble(x = 1:10)
d %>% mutate(root = map_dbl(x, \(x) sqrt(x)))
```

```
A tibble: 10 x 2
         root
      X
  <int> <dbl>
      1 1
      2 1.41
   3 1.73
      4 2
      5 2.24
      6 2.45
      7 2.65
8
      8 2.83
         3
10
     10
         3.16
```

Functions 32 / 46

Write a function first and then map it

- If the "for each" part is simple, go ahead and use map_-whatever.
- If not, write a function to do the complicated thing first.
- Example: "half or triple plus one": if the input is an even number, halve it; if it is an odd number, multiply it by three and add one.
- This is hard to do as a one-liner: first we have to figure out whether the input is odd or even, and then we have to do the right thing with it.

Functions 33 / 46

Odd or even?

• Odd or even? Work out the remainder when dividing by 2:

6 %% 2

[1] 0

5 %% 2

[1] 1

• 5 has remainder 1 so it is odd.

Functions 34 / 46

Write the function

• First test for integerness, then test for odd or even, and then do the appropriate calculation:

```
hotpo <- function(x) {
  stopifnot(round(x) == x) # passes if input an integer
  remainder <- x %% 2
  if (remainder == 1) { # odd number
    ans < -3 * x + 1
  else { # even number
    ans <- x %/% 2 # integer division
  }
  ans
```

Functions 35 / 46

Test it

```
hotpo(3)
```

[1] 10

hotpo(12)

[1] 6

hotpo(4.5)

Error in hotpo(4.5): round(x) == x is not TRUE

Functions 36 / 46

One through ten

• Use a data frame of numbers 1 through 10 again:

```
tibble(x = 1:10) %>% mutate(y = map_int(x, (x) hotpo(x)))
```

```
# A tibble: 10 x 2
      Х
  <int> <int>
      2
      3 10
   4 2
 5
      5
           16
 6
      6
            3
           22
8
      8
           28
10
     10
            5
```

Functions 37 / 46

Until I get to 1 (if I ever do)

- If I start from a number, find hotpo of it, then find hotpo of that, and keep going, what happens?
- If I get to 4, 2, 1, 4, 2, 1 I'll repeat for ever, so let's stop when we get to 1:

```
hotpo_seq <- function(x) {
   ans <- x
   while (x != 1) {
        x <- hotpo(x)
        ans <- c(ans, x)
   }
   ans
}</pre>
```

- Strategy: keep looping "while x is not 1".
- Each new x: add to the end of ans. When I hit 1, I break out of the while and return the whole ans.

Functions 38 / 46

Trying it 1/2

• Start at 6:

hotpo_seq(6)

[1] 6 3 10 5 16 8 4 2 1

Functions 39 / 46

Trying it 2/2

Start at 27:

```
hotpo_seq(27)
```

```
[1]

```

Functions 40 / 46

Which starting points have the longest sequences?

- The length of the vector returned from hotpo_seq says how long it took to get to 1.
- Out of the starting points 1 to 100, which one has the longest sequence?

Functions 41 / 46

Top 10 longest sequences

```
tibble(start = 1:100) %>%
mutate(seq_length = map_int(
    start, \(start) length(hotpo_seq(start)))) %>%
slice_max(seq_length, n = 10)
```

```
# A tibble: 10 \times 2
  start seq_length
  <int>
           <int>
     97
             119

             108
```

• 27 is an unusually low starting point to have such a long sequence.

Functions 42 / 46

What happens if we save the entire sequence?

```
tibble(start = 1:7) %>%
  mutate(sequence = map(start, \((start) hotpo_seq(start)))
```

A tibble: 7 x 2 start sequence

 Each entry in sequence is itself a vector. sequence is a "list-column".

Functions 43 / 46

Using the whole sequence to find its length and its max

```
tibble(start = 1:7) %>%
  mutate(sequence = map(start, \((start) hotpo_seq(start)))) %>%
  mutate(
    seq_length = map_int(sequence, \((sequence) length(sequence))),
    seq_max = map_int(sequence, \((sequence) max(sequence)))
)
```

```
# A tibble: 7 x 4
  start sequence seq_length seq_max
  <int> <list>
                        <int>
                                 <int>
      1 <int [1]>
      2 <dbl [2]>
3
      3 <dbl [8]>
                             8
                                    16
4
      4 <dbl [3]>
5
      5 <dbl [6]>
                            6
                                    16
6
      6 <dbl [9]>
                                    16
      7 <dbl [17]>
                            17
                                    52
```

Functions 44 / 46

Does it work with rowwise?

A tibble: 7 x 4

```
tibble(start=1:7) %>%
  rowwise() %>%
  mutate(sequence = list(hotpo_seq(start))) %>%
  mutate(seq_length = length(sequence)) %>%
  mutate(seq_max = max(sequence))
```

```
# Rowwise:
  start sequence seq_length seq_max
  <int> <list>
                                 <dbl>
                        <int>
      1 <int [1]>
      2 <dbl [2]>
3
      3 <dbl [8]>
                             8
                                    16
4
     4 <dbl [3]>
5
                            6
      5 <dbl [6]>
                                    16
6
      6 <dbl [9]>
                                    16
7
      7 <dbl [17]>
                            17
                                    52
```

It does.

Final thoughts on this

- Called the Collatz conjecture.
- Nobody knows whether the sequence always gets to 1.
- ullet Nobody has found an n for which it doesn't.
- A tree (link).
